ABSTRACT

There are three broad goals to this project. The first and primary goal is to begin the systematic development of a data base from which one could estimate the hazards to hearing resulting from exposure to blast waves or other high level impulse noise transients. To achieve this primary objective the following two objectives must first be achieved: (1) to develop a methodology to efficiently acquire data on a large number of experimental animals that have been exposed to a variety of blast wave configurations. This includes audiometric, histological and acoustic variables; (2) to develop a set of blast wave simulation devices which can reliably generate blast waves with a variable distribution of spectral energy in a laboratory environment. This report will describe progress that was achieved on each of these objectives. Before the project termination, data acquisition was completed on 70 chinchillas that were exposed to one of a series of very low frequency (125 Hz) energy-content blast wave exposure paradigms. This data represents part of the first of four phases of a parametric study that was designed to estimate the contributions of individual blast wave exposure variables on the production of hearing loss. Hearing function was measured using the auditory evoked potential (AEP) technique. The evaluation of hearing consisted of pre- and postexposure measurements of pure tone thresholds and tuning curves (masked thresholds). Quantitative and qualitative data on each experimental cochlea was obtained from the traditional surface preparation technique. The objective of this approach was to correlate the exposure variables with functional and morphological indices of trauma. The blast waves used in this first study were generated using a conventional compressed air-driven shock tube. The following blast wave parameters were studied:

1. Intensity of the blast wave. The intensity was characterized by the peak sound pressure level of the initial positive over pressure, and by the total energy (J/m^2) of the exposure. Three intensities were used; 150, 155, and 160 dB peak SPL.
2. Inter-stimulus interval (ISI) i.e., the effects of repetition rate. Rates of 1/m, 10/m, and 1/10m were used.
3. Total number of impulses (N), where N = 1, 10 and 100.

The original goals of the project were not completed because the principal investigator moved from the University of Texas at Dallas to the State University of New York at Plattsburgh. Of the 21 groups specified in the original project, 13 were completed before moving. This report includes the raw data collected for those 13 groups. The remaining eight groups will be completed at the State University of New York at Plattsburgh (DAMD17-86-C-6172) and a final summary report will contain a detailed analysis of the data from all 21 groups.

Keywords: physiological effects; stress physiology; hearing; blast waves; exposure physiology;
